Aasld treatment guidelines hepatitis b

some have just got married and is with the partner for two months, but he realized that he infected his wife with hepatitis b. so that your body fights the virus and clears the disease within 6 months according to medical experts, should stop having unprotected sex with your husband immediately or what can they really do as sex is inevitable since they share bed? hepatitis b is common all over the world, especially in many parts of the Asian and Pacific islands. in the United States, hepatitis b affects disproportionately American Asians. While Asian Americans constitute 6% of the American population, they account for more than 60% of Americans living with hepatitis b. left untreated, almost 1 out of 4 people living with hepatitis b develop serious liver problems, even liver cancer. In fact, liver cancer related to hepatitis b is a major cause of the death of cancer among American Asians. getting tested for hepatitis b can help many people access life-saving treatments that can prevent severe liver damage, people can live with hepatitis b for decades without having symptoms or feeling sick. hepatitis b is usually widespread when someone comes into contact with blood from someone who has the virus, and many people who live with hepatitis b has been infected as infants or small children. testing is the only way to know if someone has hepatitis b. anyone born regions of the world where hepatitis b is common, including Asian, Pacific and Africa islands anyone born in the United States, who has not been vaccinatedbirth, and has at least one parent born in regions of the world with high hepatitis B rate, including East or Southeast Asia Pacific Islands (excluding New Zealand and Australia) and Sub-Saharan Africa Epatite B tests identifies people living with hepatitis B so you can get medical care to help prevent severe liver damage. Talk to a doctor about getting tested for hepatitis B. Medical review by Jill Seladi-Schulman, Ph.D. — Written by Kathleen Davis, FNP on November 7, 2019Hepatitis B is a liver infection caused by hepatitis B virus (HBV). It can be acute and solve without treatment. However, some forms may be chronic, and these could lead to cirrhosis and liver cancer. HBV is a great concern for global health. In fact, in 2015, HBV-related liver disease caused approximately 887,000 deaths worldwide. Since 2016, Centers for Disease Control and Prevention (CDC) estimate that 862,000 people in the United States live with a chronic HBV infection. For most adults, HBV is a short-term condition that does not cause permanent damage. However, 2–6% of adults with HBV continue to develop a chronic infection that can potentially lead to liver cancer. About 90% of newborns with the virus will develop a chronic infection. In this article, learn more about HBV, including transmission, initial symptoms and treatment. HBV can cause infection and inflammation of the liver. A person can have HBV and transmit the virus to others without knowing they have it. Some peopleNo symptoms, some have only the initial infection, which then resolves, for others, the condition becomes chronic. in chronic cases, the virus continues to attack the liver over time without detection, resulting in irreversible liver damage. in 2017, 3.407 people reported a hbv infection to the cdc. however, accounting for people who do not report having infection, the number of acute hbv infections may have been closer to 22.100. Many hbv infections occur during childhood or childhood, this because a mother can pass hbv to her child during childbirth. However, doctors rarely diagnose hbv in childhood, as it causes few obvious symptoms. symptoms of a new hbv infection may not be noticeable in children under 5 years of age or in adults with a suppressed immune system. between 5 years and over, about 30-50% will show signs and initial symptoms. Acute symptoms appear about 60–150 days after exposure to the virus, and may last from several weeks to 6 months. a person with a chronic hbv infection may have continuous episodes of abdominal pain, persistent fatigue and joint pain. primitive symptoms if hbv causes symptoms at first, may include: painfatiguenauseavomitingloss of paindark appetiteabdominal colored urineclay sgabelliJaundice, or yellowing of skin and white eyeshbv is transmissible when blood, sperm, or another body fluid from a person with the virus enters the body of an individual who does not have it. OtherInfection may occur: when a woman with HBV gives birth to sexual activity due to sharing needles, syringes, or other drug injection devices due to the practice of unsafe tattoo techniques by sharing personal hygiene objects, such as toothbrushes and toothbrushes Health workers can be at risk through unsafe medical practices, such as reuse of medical equipment, not using personal protection, or mistakenly disposal of cutting edges. HBV cannot spread through:food or watercolor by eating zucheraChissingholding tools handleughingsneezinginsect morsti The virus can survive outside the body for at least 7 days. During this period, it may still cause infection if it enters the body of a person who has not received vaccination against it. Currently there is no cure for HBV, but the reception of the vaccine can prevent the initial infection. Antiviral drugs can treat chronic infections. If chronic HBV begins to cause permanent hepatitis damage, under a liver transplant can help improve long-term survival. However, receiving an effective vaccine and taking antiviral medication means that fewer people can end up in need of a liver transplant due to chronic HBV. There is no specific treatment, treatment, or medication for acute HBV infection. Assistance will depend on symptoms. Treatment for suspect exposure Anyone who has had potential exposure to HBV may undergo a “prophylaxis” post-exposure protocol. This consists of HBV vaccination and B immunoglobin hepatitis (HBIG).workers give prophylaxis after exposure and before acute infection develops. This protocol does not cure an infection that has already developed. However, it decreases the rate of acute infection. Treatment for chronic HBV Infection For HBV chronic infection, antiviral drugs are available. This is not a cure for chronic HBV. However, it can prevent the virus from replicating and preventing its progression in advanced liver disease. A person with a chronic HBV infection can develop cirrhosis or liver cancer quickly and without notice. If a person has no access to adequate treatment or structures, liver cancer may be fatal within months of diagnosis. People with chronic HBV infection require continuous medical evaluation and liver ultrasound every 6-12 months. This monitoring can help doctors determine whether liver damage is progressing or the condition is getting worse. The cause of HBV is hepatitis B virus which infects the body. The virus occurs in the blood and body fluids. HBV is transmissible through sperm, vaginal fluids and blood. It can also pass from a mother to a newborn during delivery. Share needles and have sex without contraception both increase the risk. People can also contract HBV when visiting a part of the world where the infection is most common. A person may spread the virus without being aware, as it may not cause symptoms. Screening is available for people at the highest risk of an HBV infection or complications due to aHBV infection. If a person has HBV, the doctor may assess the liver for damage. Hepatitis B Test A blood test can help a doctor diagnose acute and chronic HBV infection. If the test confirms the presence of HBV, the doctor may require follow-up blood tests to confirm: if HBV infection is in its acute or chronic phase the risk of liver damage if or not treatment is necessary A doctor recommends regular tests for people with chronic HBV. Once the condition reaches a chronic phase, it can change over time. Hepatitis has many different types. HBV and hepatitis C virus (HCV) have both acute and chronic forms. The main difference between HBV and HCV is how they spread from person to person. Although HCV is transmissible through sexual activity, this is rare. HCV usually spreads when the blood carrying the virus comes into contact with the blood that does not. Here, learn more about the differences between HBV and HCV. If a woman with HBV becomes pregnant, they can transmit the virus to their child. Women should inform the doctor that delivers their child who have HBV. The child should receive a HBV and HBIG vaccine within 12–24 birth hours. This significantly reduces the risk that HBV will develop. The HBV vaccine is safe to receive during pregnancy. People with a high risk of HBV include: mothers with HBV sexual partners of people with HBVpeople who engage in sexual intercourse without contraception and those who have more sexualwho have sex with men injecting illicit drugs share a family with a person who has a chronic HBV disease and public safety workers who are at risk of professional exposure to blood or contaminated bodily fluids receiving hemodialysis, which is a type of patients who treat drugs that suppress the immune system, such as chemotherapy for HIVthose cancers that come from an emerging health region with a pregnancy A vaccine against HBV has been available since 1982. People who should receive this vaccine include:all children, children and adolescents without a previous vaccination all health workers who may have exposure to blood and blood products through work or treatment personnel who suffer dialysis and recipients of transplants of resident solid organs and staff of corrective structures, half way homes and community residences that inject drugs that share a family or engage in a sexual relationship with someone who has a chronic trip The HBV vaccine takestrom of three injections. A person can receive the first injection at any age, but children should receive the first injection immediately after birth. The second shot should occur at least 1 month after the first. Adults can receive the third dose at least 8 weeks after the second dose and 16 weeks after the first. Babies should not receive the third dose before 24 weeks of age. Learn more about the benefits of hepatitis B vaccine for newborns here. How long? According to the World Health Organization (WHO), “the complete series of vaccines induces protective levels of antibody” in over 95% of infants, children and teenagers who receive it. HBV vaccine-induced immune memory can last for at least 30 years in healthy people. That said, studies on the duration of protection the vaccine offers are underway. Side effects Many people tolerate HBV vaccine well. According to the CDC, the most common side effects of the HBV vaccine are fever and pain at the injection site. A person can also experience swelling, redness and hard skin in this area. Very rarely, HBV vaccination can induce a serious type of allergic reaction called anaphylaxis. Learn more about the possible effects of HBV vaccine here. Is he alive? The HBV vaccine does not contain live viruses. This makes it safe for women to receive during pregnancy and nursing. HBV infections can cause a series of threatening complications of life, including: Cirrhosis. This causes scarring on the liver and inhibitsfunctions. It can lead to liver failure. Liver failure. Also known as final phase liver disease, this can progress quickly or during a longer period. The liver cannot replace damaged cells or function. Liver cancer. Chronic HPV increases the risk of liver cancer. Although HBV is a significant healthcare concern around the world, for most people, the vaccine provides effective protection against the virus. What is the most dangerous type of hepatitis? There are five types of viral hepatitis: hepatitis A through hepatitis E. All these are dangerous as they can potentially cause liver damage. Some types, including hepatitis A and E, cause mainly short-term infections that the immune system will eventually clarify. Other types, such as hepatitis B, C and D, can cause both acute and chronic infections. In chronic hepatitis, the immune system cannot erase the virus, so that it can continue to cause liver damage. This can lead to serious complications, such as cirrhosis, liver failure, and also liver cancer. To prevent potentially dangerous illnesses or complications from any type of hepatitis, make sure to take appropriate preventive measures and receive hepatitis vaccinations, which are available for hepatitis A and B.Jill Seladi-Schulman, Ph.D. The answers represent the opinions of our medical experts.
